

DIATOMS FROM AN UNUSUAL SITE IN CUBA

Robert McLaughlin (Santa Fe, New Mexico) and David B. Richman (Mesilla Park, New Mexico, USA)

A number of years ago the senior author acquired a sample that had been collected from a stream flowing into the Caribbean at Batabanó, La Habana Province, Cuba ($22^{\circ} 41' 55''$ N, $82^{\circ} 17' 38''$ W). The diatoms involved are a mix of freshwater, brackish water and marine species. This very rich sample produced 119 species and varieties in 39 genera. The location apparently was subject to both flow from the stream and tidal flow in the opposite direction, with brackish water species living in between. We present a list of the identified forms and their normal habitat, as well as photographs of selected specimens. False color was used to make details more visible.

We thank Richard Carter for reviewing the manuscript and for his corrections on taxonomy. If anybody sees other mistakes, please contact the junior author.

Location of Batabanó, site of collection on the Caribbean coast of Cuba. (Base map constructed by Max Bleiweiss, New Mexico State University).
